Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).

**Description****Background of the Invention**

5 [0001] Many fluoropolymer materials, such as polytetrafluoroethylene (PTFE), are thermoplastic polymers. That is, they have the property of softening when heated and of hardening again when cooled. PTFE is generally produced in the form of white powder referred to as resin. It has a higher crystalline melting point (327°C) and higher viscosity than other thermoplastic polymers, which makes it difficult to fabricate in the same manner as other plastics.

10 [0002] PTFE is a long chain polymer composed of CF<sub>2</sub> groups. The chain length determines molecular weight, while chain orientation dictates crystallinity. The molecular weight and crystallinity of a given resin prior to sintering are controlled by the polymerization process.

[0003] Currently, three different types of PTFE resins are available which are formed from two different polymerization processes. The three resins are granular polymer, aqueous dispersions, and coagulated dispersion products.

15 [0004] In the coagulated dispersion of PTFE resin, small diameter (0.1 - 0.2 micrometer) particles are coagulated under controlled conditions to yield agglomerates ranging in size from 400 to 500 micrometers in diameter. The morphological structure of these agglomerates can be considered as long chains of PTFE that are intermingled in a tangled network.

20 [0005] A known method of forming articles from fluoropolymer resins, such as PTFE, is to blend a resin with an organic lubricant and compress it under relatively low pressure into a preformed billet. Using a ram type extruder, the billet is then extruded through a die in a desired cross-section. Next, the lubricant is removed from the extruded billet by drying or other extraction method. The dried extruded material (extrudate), is then rapidly stretched and/or expanded at elevated temperatures. In the case of PTFE, this results in the material taking on a microstructure characterized by elongated nodes interconnected by fibrils. Typically, the nodes are oriented with their elongated axis perpendicular to the direction of stretch.

25 [0006] After stretching, the porous extrudate is sintered by heating it to a temperature above its crystalline melting point while it is maintained in its stretched condition. This can be considered as an amorphous locking process for permanently "locking-in" the microstructure in its expanded or stretched configuration.

[0007] It has been found that the effect caused by stretching PTFE is dependent on extrudate strength, stretch temperature, and stretch rate. According to U.S. patent 3,953,566 of W.L. Gore, products expanded at high rates of stretch have a more homogenous structure and possess much greater strength. Extrudate strength is more generally a function of the molecular weight and degree of crystallinity of the starting resin and extrusion conditions such as extrusion pressure, lubricant level, and reduction ratio. These parameters also control the degree of alignment that results from extrusion. The degree of alignment, in turn, affects one's ability to homogeneously stretch the extrudate.

30 [0008] Molecular weight and crystallinity affect the stretch characteristics, sinter profile and ultimately the final properties of the processed material. For the initial stages of fabrication, most PTFE fine powders used for ram extrusion and expansion processing are highly crystalline (>90%), as determined by IR spectroscopy, but their molecular weights may differ.

35 [0009] Low molecular weight materials tend to crystallize quickly and become highly crystalline and very brittle. In addition, the intermolecular forces between difluoromethylene groups are very low. Thus, in order to achieve adequate strength, one needs either very high molecular weight, highly crystalline material or one needs some way to disrupt the crystalline order. With a homopolymer, the best way to inhibit crystallization is to increase the viscosity of the molten material to very high values by selecting a polymer with very high molecular weight. In fact, PTFE coagulated dispersion resins that have very high molecular weights with molecular weight distributions have been developed for expanded PTFE processes.

40 [0010] In line with these considerations, the primary function of the "sintering" step is to heat the polymer above its crystalline melt point so that it can be reformed upon cooling to a low enough crystalline content to achieve the sort of mechanical properties required for the current application. To maintain a low crystalline content in the final product, the melt viscosity, corresponding to the molecular weight of the polymer, must be very high.

45 [0011] Most known methods for processing PTFE describe unilateral stretching techniques and stress the importance of stretching the fluoropolymer at rapid rates. For example, United States patent numbers 3,953,566 and 4,187,390 issued to Gore state that while there is a maximum rate of expansion beyond which fracture of the material occurs, the minimum rate of expansion is of much more practical significance. Indeed, the patents state that at high temperatures within the preferred range for stretching (35°C-327°C) only the lower limit of expansion rate has been detected. The patents estimate this rate to be ten percent of the initial length of the starting material per second. The patents go on to note that the lower limit of expansion rates interact with temperature in a roughly logarithmic fashion so that at higher temperatures within the preferred stretching range, higher minimum expansion rates are required.

50 [0012] U.S. Patent No. 4,973,609 to Browne describes another method for producing porous PTFE products by stretching at a rate of 10% per second. The patent also states that a differential structure is obtained by using an alloy

of two different fluoropolymer resins which are characterized by significantly different stretch characteristics. The resins have different molecular weights and/or crystallinities. Accordingly, the final physical properties, such as strength, of PTFE articles formed in such a way are affected by the different molecular weights and/or crystallinities of the starting resins.

5 [0013] U.S. Patent Nos. 4,208,745 and 4,713,070 also describe methods for producing porous PTFE products having a variable structure. The processes utilize a sintering step having a differential sintering profile. That is, one surface of an expanded PTFE article is sintered at a temperature which is higher than the sintering temperature of another surface. This results in fibrils being broken and provides an inherently weak material.

10 Summary of the Invention

[0014] It is an object of the invention to provide a process for producing a shaped porous article which is more truly semi-permeable than known articles formed of fluoropolymer materials. It is another object of the invention to provide such a process in which a fluoropolymer extrudate can be homogeneously stretched independently of rate. Still another object is to provide a porous article. Yet another object of the invention is to provide a porous article having a porosity which is variable in the direction of the article's cross-section.

15 [0015] These and other objects are achieved by the present invention which in one aspect features a process for producing a porous article, as defined in claim 1; preferred features of the method are defined in claims 2 to 13. The process includes the steps of providing an extrudate of a fluoropolymer material which is capable of being stretched and desirably, bilaterally stretching the extrudate along its longitudinal axis. Conditions are maintained during stretching sufficient to yield an article which is substantially uniformly stretched over a major portion of its length. These conditions include stretch rate, ratio, and temperature.

20 [0016] The stretched extrudate has a microstructure which is characterised by elongate nodes which are connected by fibrils. This microstructure is locked in by sintering the stretched extrudate while maintaining it in its stretched state.

25 [0017] Desirably, as will be described hereafter, the fluoropolymer extrudate is bilaterally stretched. That is, both ends of the extrudate are displaced along the extrudate's longitudinal axis away from a central portion of the extrudate. It has been found that this stretching method provides significant advantages over known stretching methods wherein one end of an extrudate is held stationary while only the other end is displaced.

30 [0018] The bilateral stretching is carried out at rates not greater than ten percent per second. Indeed, it has been found that stretching at rates slower than even one percent per second provides a material having an extremely desirable microstructure of nodes and fibrils, the nodes being significantly larger than nodes resulting from known processes of rapidly stretching single-resin extrudates unilaterally.

35 [0019] In carrying out the stretching step the ends of the extrudate can be displaced either simultaneously or sequentially. For example, a first end of the extrudate is displaced to a stretch ratio of not greater than two to one. That first end is then held stationary while the second end of the extrudate is displaced in the opposite direction to again result in a stretch ratio of not greater than two to one. Restricting the individual stretches to stretch ratios of not greater than two to one ensures a substantially homogeneous microstructure along a major portion of the length of the extrudate.

40 [0020] In practising the invention for producing a porous tube of polytetrafluoroethylene a preformed billet is formed of a mixture of a polytetrafluoroethylene resin and a lubricant. As above-described, the billet is extruded, the extrudate is then dried, and bilaterally stretched along its longitudinal axis under conditions sufficient to yield a tube having a substantially homogenous microstructure over a major portion of its length. The stretched tube is then sintered while being maintained in its stretched state to produce the porous tube.

45 [0021] In one embodiment of the invention, the preformed billet is formed to have a lubricant level which selectively varies in the direction of the billet's cross-section. That is, for example, the billet might have a lubricant level of fifteen percent by weight at its inner and outer surfaces and a lubricant level of approximately twenty percent at a radial position between its inner and outer surfaces. When extruded and stretched, such a billet results in a porous tube having a microstructure which varies in a controlled fashion in the direction of the tube's cross-section. This phenomenon and its advantages are described below in greater detail.

50 [0022] Accordingly, in the various embodiments of the invention, a porous article having a desired microstructure is provided by controlling the billet lubricant level, the billet reduction ratio, and bilateral stretching conditions such as stretch rate and ratio. These steps avoid the problems such as weak material which are associated with known resin-blending and varied-profile sintering techniques.

55 [0023] In another aspect, and as defined in claim 20, the invention features a tube formed of an expanded porous fluoropolymer material. The material has a microstructure characterized by ring shaped nodes interconnected by fibrils. An important feature of this aspect of the invention is that substantially all of the nodes each circumscribes, at least in part, the longitudinal axis of the tube and extends from the inner to the outer surface of the tube wall, thereby creating between the nodes continuous through-pores from one surface to the opposite surface.

[0024] Still further, the invention provides a prosthesis as defined in claim 14. Such a prosthesis features a tube formed of porous fluoropolymer material characterized by a structure of nodes and fibrils wherein the nodes are radially oriented and the fibrils extend substantially parallel to the axis of the tube between successive nodes, the nodes and fibrils forming pores having radially tapering size distribution conducive to tissue through-growth.

5 [0025] These and other features of the invention will be more fully appreciated by reference to the following detailed description which is to be read in conjunction with the attached drawings.

Brief Description of the Drawings

10 [0026]

Figure 7B is a photomicrography of a tangent section taken at the interior of the structure of Figure 7,

40 Figure 7C is a photomicrograph of a tangent section taken of the exterior of the structure of Figure 7,

Figure 8A schematically illustrates a tube preform with layered material of radially decreasing lube level, and

45 Figures 8B and 8C are photomicrographs of tangential sections of a tube formed from the preform of Figure 8A, taken in the regions corresponding to B and C, respectively, of Figure 7.

Detailed Description

50 [0027] As stated above, in one aspect the invention features a process for producing a shaped porous article. A significant feature of the process is that an article having a homogeneous microstructure is formed independently of the rate at which it is stretched.

[0028] By homogenous microstructure, in this patent application, it is intended to convey first that the microstructure of the article, including relatively dense nodes separated by relatively light connecting fibrils, is relatively uniform along at least one dimension, e.g., the length of the article, although as will be explained below, aspects of microstructure may be, and preferably are, intentionally varied in another direction, e.g., in cross-section of the article.

55 [0029] Various fluoropolymer resins are suitable for use in the present invention. For example, polytetrafluoroethylene or copolymers of tetrafluoroethylene with other monomers may be used. Such monomers may be ethylene, chlorotrifluoroethylene, perfluoroalkoxytetrafluoroethylene, or fluorinated propylenes such as hexafluoropropylene. In particu-

lar, however, polytetrafluoroethylene (PTFE) works well. Accordingly, while the inventive process can be utilized to produce porous articles formed of various fluoropolymer materials, the following description pertains specifically to the formation of an article from PTFE resin.

5 [0030] For purposes of the present invention, all fluoropolymers that require a lubricant/extrusion aid and are capable of being expanded can be used. However, it is preferred to use highly crystalline, high molecular weight resins to achieve maximum strength. When PTFE is used, resin of a molecular weight between 5,000,000 and 70,000,000 is suitable.

10 [0031] It should be noted, however, PTFE does not dissolve in any common solvent; therefore its molecular weight cannot be measured by the usual methods. According to the Encyclopedia of Polymer Science and Engineering (Wiley and Sons, 1989), though, the following relationship has been established between number-average molecular weight (M<sub>n</sub>), for molecular weights between  $5.2 \times 10^5$  and  $4.5 \times 10^7$ , and the heat of crystallization ( $\Delta H_c$ ) in Joules/gram (calories/gram).

$$15 \quad M_n = (2.1 \times 10^{10}) \times \Delta H_c^{-5.16}$$

[0032] Accordingly, by determining the heat of crystallization of a given PTFE resin, a number average molecular weight of the resin is determined using this relationship.

20 [0033] As with known methods of processing PTFE, the invention utilizes a preformed billet which comprises a PTFE resin mixed with an organic lubricant. Various lubricants are suitable such as naphtha, ISOPAR-G and ISOPAR-H available from Exxon Corporation. Low odor paraffin solvents can be used as well. The blended resin is compressed at low pressure (less than 69 bar (1000 PSI)) into a tubular billet of approximately one third of the resin's original volume. Billet forming processes are generally known in the art.

25 [0034] As discussed above, extrusion conditions have a significant effect on the resulting extrudate's reaction to being stretched. In particular, once a resin of a given molecular weight and crystallinity has been selected, extrudate qualities are controlled by the level of lubricant mixed with the resin to form the billet, the reduction ratio at which the billet is extruded and the extrusion pressure. These are believed to influence the micromechanical properties of the extruded article because these parameters affect the degree to which the molecular chains of PTFE align themselves during extrusion.

30 [0035] The process of the invention is most effective when using preformed billets ranging in lubricant level from between 8 to 25 percent by weight to produce an extrudate well adapted for the inventive stretching process.

35 [0036] When PTFE extrudate is subjected to an external tensile force, such as during stretching, the intermingled network of PTFE particles separate. Accordingly, the force required to separate these particles, and hence stretch the extrudate, is dependent upon the degree of intermingling of the PTFE particles. The longer the polymer chains (higher molecular weight), the greater the amount of intermingling that will occur and, therefore, the greater the force that will be required to separate the coagulated dispersion particles.

40 [0037] Two other extrusion parameters having an effect on a resulting extrudate's reaction to stretching are reduction ratio and extrusion pressure. The range of suitable reduction ratios is bounded at its lower end by the minimum reduction ratio permissible which provides an extrudate of sufficient strength so as not break during stretching. At its upper limit, the range of suitable reduction ratios is bounded by the maximum ratio permissible which provides an extrudate that is amenable to being homogeneously stretched. Accordingly, experimentation has shown that for purposes of the present invention the preformed billet should be extruded to a reduction ratio of between approximately 50:1 and 600:1. A preferred reduction ratio is between approximately 200:1 and 400:1.

45 [0038] Reduction ratio and stretch characteristics are interrelated since the force required to deform a PTFE extrudate and form fibrils from the nodes is related to how the material was aligned (packing density) during extrusion. Fibrils are not formed as easily from nodes with high reduction ratio extrudates as they are with low reduction ratio extrudates. This is believed to be because internal forces are much higher in high reduction ratio extrudates.

50 [0039] The third extrusion parameter which has a significant effect on the resulting extrudate's properties upon being stretched is extrusion pressure. While extrusion pressure is, to a certain extent, related to reduction ratio, by varying lubricant level, extrusion pressure can be varied independently of reduction ratio. While measured extrusion pressure will vary depending upon the type of extrusion equipment being used, the range of suitable extrusion pressures to practice the present invention will be apparent to those skilled in the art. For example, pressures between approximately 413 bar (6000 PSI) and approximately 690 bar (10,000 PSI) have been used successfully for the practice of the invention.

55 [0040] Once an extrudate has been produced according to the above described parameters, in accordance with the inventive process it is stretched under conditions sufficient to yield an article that is uniform over a major portion of its length. Stretching processes are characterized in terms of stretch rate and stretch ratio. Stretch rate refers to the percentage change in length of the extrudate per unit time. In the case of a fifty centimeter long extruded tube, for

example, stretching five centimeters per second results in a stretch rate of ten percent per second. The percentage change is calculated with reference to the initial length of the extrudate.

[0041] Stretch ratio, on the other hand, is not time dependent but merely refers to the ratio of the final length of the stretched extrudate to that of the initial length of the unstretched extrudate. Accordingly, stretching a fifty centimeter long extruded tube to one hundred centimeters, results in a stretch ratio of 2:1 regardless of the duration of the stretch.

[0042] With this in mind, it is an important feature of the invention that extruded materials are stretched to form porous articles independently of stretch rate. In certain instances the process is dependent on stretch ratio. As stated above, known methods for processing fluoropolymer materials teach that stretching must be carried out at a rate generally exceeding approximately ten percent per second. In accordance with the invention, however, homogeneous articles are produced at stretch rates not greater than approximately ten percent per second. Indeed, the preferred rate of stretching ranges from approximately 0.5 percent per second to approximately 10 percent per second.

[0043] To stretch an extrudate, the extrudate must be placed in tension. This is done by applying opposed forces to the ends of the extrudate. The level of force applied to the extrudate, and hence the rate at which the extrudate stretches, determines how the above-described intermingled network of PTFE particles unravels. In known methods for stretching PTFE, force is applied to place the extrudate in tension by displacing one end of the extrudate with respect to the other end. At stretch rates lower than ten percent per second, this method of stretching cannot uniformly stretch the extrudate to greater than a 2:1 ratio. To the contrary, at greater ratios the material stretches preferentially at its moving end. The fixed end of the material, on the other hand, experiences significantly less stretching.

[0044] In accordance with the invention, on the other hand, bilateral stretching results in more even force distribution along the length of the extrudate and produces a more homogeneously stretched material. It has been found that stretching bilaterally, that is, displacing both ends of the extrudate away from the middle of the extrudate, provides a material that is homogeneously stretched over the majority of its length independent of the stretch rate.

[0045] After the extrudate has been bilaterally stretched it is sintered by heating it above its crystalline melting point under tension. As discussed above, this locks in the microstructure of the material and completes the process of producing the porous article.

[0046] Figure 1 is a schematic representation of a porous tube 10 formed by the above described bilateral stretching process. For purposes of description, the microstructure of the tube 10 has been exaggerated. Accordingly, while the dimensions of the microstructure are enlarged, the general character of the illustrated microstructure is representative of that microstructure prevailing in an article formed by the inventive process.

[0047] The tube 10 includes a microstructure characterized by elongate nodes 12 interconnected by fibrils 14. A significant feature of the tube 10 is that the nodes 12 are ring-shaped to form, in effect, a series of washer-type, or plate-like solid bodies circumscribing the tube's longitudinal axis L. The nodes 12 are oriented generally radially, i.e., perpendicularly to the axis of stretching, represented by arrows T which is coincident with the longitudinal axis L.

[0048] Another significant feature of the tube's microstructure is that substantially all of the nodes 12 extend along a transverse axis t from an inner surface 16 of the tube to an outer surface 18 of the tube. This dimension of the nodes 12 along the inside-to-outside direction is significantly larger than the corresponding dimension of nodes formed by conventional single-resin fluoropolymer processing methods. Such nodes are randomly arranged and may be characterized by a transverse axis which is generally oriented perpendicularly to the axis of stretch. Notably, however, the nodes of these known structures are considerably shorter and smaller than nodes produced in accordance with the present invention. Indeed, the above-referenced U.S. patents to Gore note that nodes formed by that known technique generally range in size from smaller than one micron to approximately 400 microns.

[0049] Unlike the short, randomly stacked nodes and microfibrillar spaces formed by conventional single-resin fluoropolymer stretch or expansion processing, the method of the present invention provides a microporous structure having microfibrillar spaces which define through-pores or channels extending entirely from the inner to the outer wall of the expanded extrudate. These through-pores are perpendicularly oriented internodal spaces which traverse from one surface to another.

[0050] As discussed below in greater detail, by varying lubricant levels such intermodal through-pores are preferentially altered in accordance with the present invention such that the surface pore on one surface is made to be larger or smaller than the surface pore on the opposing surface.

[0051] A longitudinal cross-section view of a tubular article formed by the process of the invention is shown in Figure 2. There, it can be seen that the present invention produces an article having a microstructure characterized by elongate nodes which are substantially larger than the nodes of materials produced by known single-resin forming methods. Indeed, the nodes shown in Figure 2 consistently range in size from approximately 500 microns to approximately 900 microns. Substantially all of the nodes of the article shown in Figure 2 extend from the inner surface of the tubular article to the outer surface of the tubular article, thereby creating through-pores substantially all of which traverse from one surface of the article to the other.

[0052] Figure 3 is a radial cross-section view of the tubular article shown in Figure 2. There it can be seen that while the nodes are generally oriented perpendicularly to the axis of stretch, as represented in Figure 1, they are not perfectly

flat and, therefore, a radial cross-section cuts through many nodes. Accordingly, while the schematic representation in Figure 1 is useful for purposes of explanation, the scanning electron microscope photographs in Figures 2 and 3 are more accurate depictions of the microstructure of a product produced by the inventive process.

[0053] Products provided by the process of this invention are suitable for a wide range of biological applications such as for vessel implants or organ wall grafts. In particular, as described below, vascular grafts formed by the process of the invention enjoy various advantages. Indeed, the process of the invention is well suited for the formation of the various biological devices described in the following commonly assigned and co-pending United States Patent Applications: U.S.S.N. 760,753 for "IMPLANTABLE PROSTHETIC DEVICE FOR THE DELIVERY OF A BIOACTIVE MATERIAL"; U.S.S.N. 760,716 for "MANUALLY SEPARABLE MULTI-LUMEN VASCULAR GRAFT"; U.S.S.N. 760,728 for "IMPLANTABLE PROSTHETIC DEVICE HAVING INTEGRAL PATENCY DIAGNOSTIC INDICIA"; U.S.S.N. 760,717 for "POLYLUMENAL IMPLANTABLE ORGAN"; and U.S.S.N. 760,718 for "SELF-SEALING IMPLANTABLE VASCULAR GRAFT" all of which were filed 16 September 1991. The US patents corresponding to these applications are respectively numbered 5 411 550; 5 197 976; 5 320 100; 5 370 681 and 5 192 310.

[0054] As stated, several structural, clinical and biological advantages accrue from the microstructure engendered by the inventive process. For example, as discussed below in greater detail with regard to the various examples, larger node size provides a structure having a significantly improved radial tensile strength. Also, tubes formed by the inventive process have improved burst pressure and suture strength characteristics. The flat ring-like node structure imparts significantly more flexibility, without kinking, than conventional fluoropolymer processes, in addition to providing superior resistance to radial twist compression (colloquially known as "torque twist"). The tubular article formed by the process of the invention allows a significant degree of bending or radial twist, before experiencing lumen collapse or kinking, unlike conventional fluoropolymer articles which exhibit significantly less resistance to "torque twist" or "bending." Conventional articles, therefore, kink under smaller stress loads than do the articles of the current invention.

[0055] Additionally, the method of the current invention produces articles which exhibit significantly more resistance to compression than conventionally processed articles. This provides more resistance to luminal collapse under equivalent stress loads. The articles provided by the invention also exhibit increased flexibility for enhanced drapability, or ability to bend more readily, without restricting luminal cross-sectional area, thereby improving ease of handling during surgery, while not increasing stress on the points of attachment and fixation. The ring like nodal architecture of the invention also produces tubular structures with significantly more resistance to tearing or splitting in the horizontal direction, as compared to conventional non-reinforced fluoropolymer tubular articles.

[0056] For experimentation, an extrudate was prepared by blending PTFE resin (Fluon CD-123 obtained from ICI Americas) with "ISOPAR-H" odorless solvent (produced by Exxon Corporation) used as an extrusion aid at a level of 150 cc of solvent per 0.45 kg (pound) of resin. The blend was compressed into a tubular billet, heated to 300°C, and extruded into a 6 mm I.D. by 7 mm O.D. tube in a ram extruder having a reduction ratio of about 149:1 in cross-sectional area from billet to the extruded tube. The volatile extrusion aid was removed by drying in a heated oven prior to stretching.

[0057] To demonstrate the advantages of bilateral stretching, samples of the tubular extrudate were then stretched various ways as discussed below.

#### METHOD 1

[0058] An apparatus was developed that allowed samples of the tubular extrudate to be stretched at controlled rates and temperatures. The apparatus consisted of two clamps for holding the tube, one clamp held fixed within the oven and another clamp attached to a chain drive coupled to a variable speed motor. The tube was stretched an amount equal to 50% of its original length at a rate of approximately 10% per second. The fixed and moveable ends were then inverted and the stretching step repeated. The stretch and inversion steps were repeated until the extrudate sample had been stretched to a final stretch ratio of three to one. The oven temperature was then raised to 370°C for ten minutes while the samples were held clamped.

#### METHOD 2

[0059] An apparatus was developed that allowed both ends of the extrudate to be displaced simultaneously, at a controlled temperature and rate. The apparatus included two clamps independently mounted to two slide drive systems. Following mounting to the stretch apparatus, both ends of the sample were displaced simultaneously at equal speeds in opposite directions for a selected distance. The applied stretch rate using the combined displacements rates from each end was calculated to be approximately 10% per second. The final stretch ratio was approximately three to one.

METHOD 3

[0060] The apparatus described in Method 2 was used to displace each end of the extrudate sequentially. That is, first one end of the extrudate was held fixed while the other was displaced a given distance at a constant speed, then, without inverting the sample, the previously displaced end was held stationary while the formerly stationary end was displaced the same distance at the same speed. Again, the sample was stretched at a rate of approximately 10% per second to a final ratio of approximately three to one.

[0061] Samples produced by the above described methods were then tested along with commercially available PTFE tubes produced by conventional, unilateral stretch techniques, the results appearing below.

[0062] Where A is longitudinal tensile strength in N/mm<sup>2</sup> (pounds per square inch);

where B is radial tensile strength in N/mm<sup>2</sup> (pounds per square inch);

where C is water entry level in bars (pounds per square inch);

where D is radial burst pressure in bars (pounds per square inch);

where E is ethanol bubble point in bars (pounds per square inch); and

where F is suture strength (in grams) for a 2mm bite.

[0063] Further, tubular extrudate samples as produced above were bilaterally stretched, displacing both ends simultaneously, at other stretch rates. Again, the stretch rates were calculated by combining the displacement rates of both ends of the extrudate. Tests performed on samples produced in this manner yielded the results detailed below.

[0064] The data clearly indicate that enhanced radial strength and suture strength along with a corresponding decrease in Water Entry Pressure and Ethanol Bubble Point, result from the preferred bilateral stretching process.

[0065] For purposes of evaluating homogeneity, additional tubular extrudate samples were marked at 12.7 mm (1/2") spaced intervals using a permanent marker. The samples were mounted and stretched either unilaterally with one end held fixed throughout the stretching process or bilaterally in which both ends were displaced simultaneously. After stretching at rates equal to or lower than 10% per second the samples were sintered and analyzed by measuring the distance between the marks along the sample lengths. This distance, divided by the original spacing yields a local measure of the expansion ratio. The results detailed below indicate that at low rates of stretch bilateral stretching produces a structure which is more uniform than unilaterally stretched products. That is, with the bilaterally stretched samples, each 12.7 mm (half inch) segment stretched an amount comparable to all segments through the length of the sample. Each unilaterally stretched sample, on the other hand, stretched preferentially at its moving end, often by

a factor three to five times greater than that of its restrained end.

[0066] It can be seen that at a rate of 10% per second, bilaterally stretching an extrudate to a ratio of 3:1 in accordance with the invention yields an achieved expansion factor that varies by under 10% along the length of the stretched extrudate. Bilaterally stretching to a 4:1 ratio at this rate yields a variation of less than 8%.

[0067] Bilaterally stretching at 5% per second yields similar uniformities in achieved expansion factor. Moreover, such variations as there are, appear to be distributed in a more spatially uniform way.

[0068] These results show that with unilateral stretching at the above-noted rates and ratios, a far greater variation in achieved expansion results. In particular, the results show that at these rates and ratios, a unilaterally stretched sample stretches preferentially at its moving end.

[0069] In another embodiment of the invention, a porous article is formed utilizing a preformed billet such as billet 50 shown in Figure 4. Billet 50 includes radial inner portion 52 and radial outer portion 54. A significant feature of billet 50 is that while radial portions 52 and 54 comprise the same resin, different lubricant properties prevail in the portions. For example, different types of lubricant, different molecular weight lubricants of the same type, lubricants of different viscosity, or a single lubricant but at different relative proportions may be used.

[0070] The formation of layered preform billets is generally known in the art. For example, various known techniques have been used to produce extrudates having a conductive layer in electronic applications or a colored layer in general tubing applications. U.S. Patent No. 4,973,609 assigned to Browne describes a layering technique using different resins.

[0071] In accordance with this aspect of the present invention, the microstructure of an extruded and expanded PTFE article is controlled using a single resin with a varying lube characteristic, preferably the lube level, through the preform billet. For instance, the sample shown in Figures 5A through 5C was produced using a single PTFE resin that was preformed in a layered fashion at two different lube levels across its cross-section and processed according to the above described bilateral stretching process.

[0072] Figure 5A is a longitudinal cross-section view of a wall 60 of a tubular article formed utilizing the billet 50 in accordance with the above-described inventive process. As can be seen in the Figure, the material forming the wall 60 is characterized by a microstructure of large nodes 62A and small nodes 62B interconnected by fibrils 64. This results due to the inner radial portion 52 of billet 50 having a lower lubricant level than the outer radial portion 54. That is, lower lubricant levels result in smaller, more closely spaced nodes.

[0073] Several advantages accrue from the structure of wall 60. For example, by forming a tube having porosity at an inner surface 66 (FIGURE 5B) which is smaller than the porosity at an outer surface 68 (FIGURE 5C), a vascular graft is provided which defines an efficient flow channel at its inner surface while fostering improved cellular ingrowth at its outer surface.

[0074] It should be understood that in addition to the illustrated embodiment, billets can be formed in accordance with the present invention having lubricant properties which vary in a selected pattern through the cross-section to achieve desired pore or channel distribution. For example, by forming a tubular billet which has a lubricant level which is different at a radial position of the cross-section from the lubricant level at another position, e.g., the inner or outer surfaces of the cross-section, and by carefully extruding a preform from the billet, a unique product is formed. For example, a tubular article having a wall 70, such as shown in Figure 6, can be formed by this method. Note that the wall 70 has relatively large pores at its inner and outer surfaces 76 and 78 but includes a barrier region 80 of smaller pores between the inner and outer surfaces. Such a structure used as an implant or vascular graft is expected to promote cellular ingrowth from both sides of the wall 70 while preventing cellular growth completely through the wall.

[0075] From the fact that stretching of the extrudate yields an article with pore structure corresponding to the lube distribution of the preform, it appears that flow in the long tapered extrusion head is highly laminar. Such flow can result in a uniformity of PTFE molecular orientation. Applicant expects this property to result in an extrudate that, after sin-

tering, will have high tensile strength, as compared to conventionally extruded materials.

[0076] For biological applications, the unique through-pore orientation created by the individual nodal spaces is exploited, for example, to either increase or decrease the migration of certain cellular and or biological materials directly into or onto the inventive tubular structure. This results in improved biocompatibility. For example, it is well documented that specific cell types penetrate, grow into, or onto porous fluoropolymer structures. By providing a matrix of large, oriented nodes to present non-tortuous pathways, full cellular penetration is possible, without "dead ended" channels. This offers a significantly improved cellular environment, for example, to promote the growth of morphologically complete capillaries. The provision of large-entry channels with a taper offers similar advantages, with the added feature of precisely limiting the depth of tissue penetration. Hence the hybrid nodal structure design of this invention offers many structural, physical and biological characteristics not found with other, well documented pure fluoropolymer, composite or coated tubular articles.

[0077] In accordance with the invention, therefore, methods and materials are provided for the formation of biological implants having enhanced structures and tissue support features. Both organ wall grafts and vessel implants can be formed by practice of the invention. Representative methods of fabricating tube structures with taper nodal geometry will now be briefly described.

#### METHOD 4

[0078] PTFE resin identified as Fluon CD-123 obtained from ICI Americas was blended in two separate containers with 98 cc and 150 cc, respectively, per 0.45 kg (pound) of resin, of an odorless mineral solvent, identified as Isopar-H produced by Exxon Corporation. The solvent serves as a lubricant for extrusion of the resin, in a manner well known in the art. The two resin/lube mixes were then separately poured into a preforming cylinder in concentric layers to form a billet or preform 50 as shown in Figure 4. Inner layer 52 of extrusion preform 50 contained the lower lube level (98 cc lube per 0.45 kg) resin. Outer layer 54 of preform 50 contained the higher lube level (150 cc per 0.45 kg) resin. A core-rod cylinder was fitted over the core rod of the preforming cylinder to separate the layers during pouring. The cylinder was removed after pouring was completed, and the extrusion preform, or billet, was formed by compacting the layered mass under a compaction pressure of 41.3 bar (600 psi), to produce a dense preform billet having a concentric stepped concentration of lube level.

[0079] The preform billet was then inserted into a ram extruder and extruded into a 4 mm I.D./5.3 mm O.D. tube, the ram extruder having a reduction ratio of 350:1 in cross-sectional area from preform to extruded tube. 38 cm (fifteen inch) samples were cut from the tubular extrudate and allowed to bake at 300°C for five minutes prior to stretching in order to remove the lubricant, which was a volatile extrusion aid. The samples were then stretched at 300°C at a rate of 0.5% per second to a length of 1.12 m (45 inches). Sintering was effected by clamping the tube ends and heating the restrained samples to a temperature of 370°C for four minutes.

[0080] Figure 7 indicates in schema a tube structure 150 formed in this fashion having interior surface 152 and exterior surface 154, with the section lines A, B, and C identifying radial and inside and outside sections for which electron micrographs of a prototype tube are discussed below.

[0081] Indicated sample sections of the expanded tube were then prepared and subjected to electron micrography, as shown in Figures 7A-7C.

[0082] As best seen in the radial section; Figure 7A, the inner surface 152 of a tube prepared in this manner has a more frequent node structure than the outer surface, with nodes spaced almost twice as frequently along the tube axis as at the outer surface 154. Fibril length is therefore necessarily shorter, but both inner and outer regions have full, densely-arrayed fibrils with none of the coalescence that characterizes the differential-heating approach to node tailoring of the prior art. Moreover, the diameter of the fibrils is essentially the same at the inside and outside regions.

[0083] As seen in Figure 7C, the node-fibril structure in the radially outer portion of the tube is characterized by large intact node bodies, spaced 40-80 micrometers apart, whereas that of the radially inner portion has a node spacing in the range of 25-50 micrometers (Figure 7B). The overall form of the nodes is that of flat plates oriented perpendicular to the tube axis, and extending in partial or complete annuli about the central lumen of the tube. The inside edges of the nodes may be seen to be somewhat fragmented or frayed in appearance, while still preserving the overall plate-like form and radial orientation of the outer portion, despite their closer spacing.

[0084] The resulting structure therefore has through-pores extending substantially continuously from the inside to the outside. In addition, applicant has found this material to have a strength comparable to conventional stretched PTFE products fabricated using much higher stretch rates.

#### METHOD 5

[0085] PTFE resin as used in Method 4 was blended in two separate containers with 104 cc and 150 cc, respectively, of Isopar-H per 0.45 kg (pound) of resin. The two resin/lube mixes were then separately poured into a preforming

cylinder in concentric layers as shown in Figure 8A with the inner layer 52' of extrusion preform 50' comprised of higher lube level (150 cc lube per 0.45 kg) resin and the outer layer 54' of preform 50' comprised of lower lube level (104 cc per 0.45 kg) resin. As before, a core-rod cylinder was fitted over the core rod of the preforming cylinder to separate the layers during pouring and was removed after pouring was completed. An extrusion preform was then formed by compacting the layers under a pressure of 41.3 bar (600 psi).

5 [0086] The preform was then extruded into a 4 mm I.D./5.6 mm O.D. tube in a ram extruder having a reduction ratio of 220:1 in cross-sectional area from preform to extruded tube. 38 cm (15 inch) samples were cut from the tubular extrudate and allowed to bake at 300°C for five minutes prior to stretching in order to remove the extrusion lubricant. The samples were then stretched at a rate of 2.5% per second to a length of 1.12 m (45 inches), followed by sintering

10 by heating the restrained samples to a temperature of 370°C for four minutes.

[0087] As shown in Figure 8B, a tangential section at the inner region of a tube so formed has a nodal structure of relatively large, ring-like sheets oriented perpendicular to the tube axis. As indicated in Figure 8C, the nodal structure at the outer region retains the same orientation, but becomes more closely spaced. Thus, the relative porosity varies, from the inside to the outside, in a sense opposite to that of the tube structure produced by Method 4.

15 [0088] It will be appreciated by those skilled in the art that in each of the foregoing embodiments the structure of nodes and fibrils results in a pore structure wherein interstitial spaces of tapering aspect extend entirely, or substantially entirely through the wall of the tube.

[0089] As described above, extrusion from a billet formed with varying levels of lubricant produces a preform, and after stretching results in an article, having a pore structure that varies. Applicant expects a similar effect to result from 20 use of a billet wherein, rather than varying the level of lubricant, one position (e.g., inside, or outside) is formed using a lubricant of different density or a different composition than is used in the other portion. For the example, the preform may be made using a layer of PTFE material mixed with an Isopar-like lubricant, e.g., a simple hydrocarbon solvent of density approximately .6, and a layer of the same PTFE material mixed with a heavy oil, such as a more viscous hydraulic pump oil or a glycerin-containing fluid. Following extrusion, both lubricants are baked out, and the final 25 stretched or unstretched article is sintered to fix its microporous structure.

[0090] Related effects are also expected when forming a billet wherein one portion has its lubricant less uniformly dispersed in or mixed with the resin. In that case, the voids left upon baking out the lubricant may be expected to result in regions having different nodal size in the coarsely-mixed extrudate than in the well-mixed extrudate. Thus, the invention is understood to include articles formed by extrusion of two different extrusion materials, wherein the materials 30 have the same resin, and differ only in type, quantity, uniformity or other property of the lubricant included in the material.

[0091] It will be further understood that while the invention has been described with reference to extrusion of a billet formed of different concentric cylinders to make a tubular item, billets of other shape may advantageously be used to extrude articles of other aspect or shape, such as multi-lumenal solid or perforated bodies as described in applicant's aforesaid co-pending United States patent applications.

35 [0092] Furthermore, a tubular product as described above, may be slit longitudinally to provide a belt-like sheet, and one or more such sheets may be joined or assembled in a multi-layer stack to form an article having through-wall porosities of two or more successive or opposed tapers. In other constructions, a tube as described above may be pressed flat so that it forms a strip two layers thick, with a larger (or smaller) pore structure at its center than at either outside surface.

40 [0093] According to a principal aspect of one presently preferred embodiment of the invention, a structure employed in a vascular graft, is formed of PTFE tube having a lower inside than outside porosity, the variation being introduced by extrusion from a billet having higher outside lube levels, followed by stretching and sintering. Advantageously, the node structure of plate-like sheets oriented perpendicular to the axis of the tube permits deep cellular ingrowth, and provides a flexible anti-kink and non-collapsing lumen structure, yet prevents blood leakage at the smaller-pored wall.

45 [0094] In a proof-of-principle experiment carried out with a tubular prosthesis made in accordance with Method 4 above, the tubes were implanted in the carotid artery of dogs and left in vivo for extended periods to assess patency, cell growth and tissue compatibility. In implants that remained patent, tissue ingrowth had progressed by forty-five days such that morphologically complete normal capillaries had grown through the entire thickness of the tube wall. This single-resin expanded fluoropolymer graft thus appeared to demonstrate, for the first time known to the inventors, an 50 artificial vessel replacement structure essentially capable of supporting natural vessel wall regrowth extending not only along the interior surface, but between the inside and outside surfaces.

[0095] It is expected that in other areas where it has historically been possible to achieve tissue growth only for limited times or to limited depths, different forms of prosthesis made in accordance with the above pore-tailoring and uniformity-promoting processes will support enhanced natural or seeded growth of other cell types to form replacement 55 tissue for diverse organs, vessels and tissue structures.

[0096] For example, the invention contemplates that an organ prosthesis, partial organ, patch, graft, or organlike structure be formed of material having the desirable permeability to fluids on a macroscopic scale and porosity to receive cellular growth, possibly in connection with one or more lumena defining flow paths therethrough for carrying

blood and/or other biological fluids. For a discussion of a range of shaped porous articles intended for diverse such uses, reference is made to applicant's above-mentioned patent applications. Such shapes may be configured to constitute grafts, intended to patch over and regenerate regions of tissue that have been lost to trauma, disease or surgery, or may constitute entire organs. Furthermore, such prostheses need not be patched into an existing organ, but may, for example, be seeded with culturable cells, cultured and implanted into a well-vascularized region capable of supporting tissue growth and of receiving the material expressed by the tissue for circulating it in the bloodstream. Thus, the inventive prosthesis provides a bioreactor for producing biological material, the walls and lumens serving to sustain the culture and allow exchange of cultured products in the body.

[0097] For this latter application, the tailored pore structure of articles of the present invention allows tissue growth and exchange of expressed bioactive materials, without allowing exogenous cells to circulate and without allowing immunity-mediating cells to reach the cultured tissue. The cellular containment thus diminishes the likelihood of inducing a whole body rejection or cell-mediated immune response. By way of example, an artificial pancreas for insulin replacement therapy may be formed by seeding a closed multiluminal article to grow islets of Langerhans, with the cell products and secretions entering blood circulating through one or more of the lumena. In this case, it is desirable to culture the cells and supporting material in vitro, and then implant the functioning culture body to initiate insulin or other replacement therapy. In other examples of this method of use of articles of the present invention, endothelial cells may be cultured to provide their cell products into the bloodstream.

[0098] Another class of articles of the present invention having varying pore structure is the class of filters or filtration units. For this application, the presence of a tapering pore structure can be used, for example, in different orientations to prevent particles from reaching and clogging subsurface regions of a filter membrane, or to allow greater fluid pressure through the depth of a filter membrane, in each case having the effect of enhancing overall the filter's lifetime, capacity or filtration rate.

[0099] Still another class of articles directly pertaining to the present invention is that of culture beds or bioculture reactors, wherein an extrudate, e.g., a porous tube or sheet made in accordance with the invention, serves as the anchoring structure for cellular material - tissue or microorganisms - that synthesize an enzyme or other substance which is the end product of the process. In this case, the porosity, possibly in a tubular or multilumenal structure may allow the transport of nutrients to one side of the article, and the harvesting of product at another or the same side, without having to break up the cell mat to affect such feeding or harvesting.

30

### Claims

1. A method of producing a shaped porous article, comprising the steps of
  - 35 forming a billet (50, 50') of a single fluoropolymer material and a lubricant in which a variation of the lubricant has been established along a dimension of the billet, (50, 50')
  - extruding the billet to form an extruded article having a shape and a lubricant that varies corresponding to the variation of lubricant in the billet, (50, 50')
  - 40 removing lubricant from the article and stretching the extruded article to form a porous article (10, 70, 150) with predetermined pore sizes in different regions thereof, wherein variations of pores occur in regions where the extruded article had variations of lubricant, and
  - sintering the porous article in its stretched state to fix its dimensions, thereby forming a sintered porous article (10, 70, 150) of a single fluoropolymer material having different porosities in predetermined regions thereof.
- 45 2. The method according to claim 1, wherein the step of forming the billet (50, 50') includes forming with a lubricant level that varies along a direction through the billet from a level no lower than about ten percent to a level no higher than about twenty-four percent.
3. The method according to claim 1, wherein the billet (50, 50') is formed with lubricant levels in different regions selected to provide an article having a pore size distribution that permits tissue growth on at least a portion of the article without permitting fluid leakage through the article.
4. The method according to claim 1, wherein the step of sintering is performed to uniformly sinter the porous article at the sintering temperature of said single-resin fluoropolymer.
- 55 5. The method according to claim 1, wherein the step of forming a billet (50, 50') includes forming a billet in plural layers, at least two layers having different levels of lubricant.

6. The method according to claim 1, wherein the step of extruding comprises forming a tubular extruded article.
7. The method according to claim 6, wherein the tubular extruded article is formed having a wall-thickness of under two millimetres.
- 5 8. The method according to claim 6 or 7, wherein the step of stretching is performed by stretching at a rate below approximately two percent per second.
9. The method according to claim 1, wherein the step of extruding includes extruding a tubular extruded article having a lumen, and the step of stretching includes stretching so as to produce radially-oriented nodes (12) extending about the lumen and interconnected by fibrils (14), spaces between the nodes defining through pores from said lumen to an outer surface (18) of the article.
- 10 15. The method according to claim 1, wherein the step of forming a billet (50, 50') includes forming a billet having different lubricants at different positions along its cross-section.
11. The method according to claim 10, wherein the different lubricants are lubricants of different density or different viscosity.
- 20 25. 12. A method according to claim 1, wherein the shaped porous article (10, 70, 150) is a prosthetic article, and the variation of lubricant is a selected variation of the lubricant level in the direction of the cross-section of the article.
13. The method according to claim 1, wherein the variation of lubricant occurs along a cross-section from inside to outside of said billet (50, 50'), and the step of stretching the extruded article introduces a tapered pore structure extending from inside to outside of the article, the pore structure extending from smaller pores to larger pores, wherein larger pores are formed in regions where the article has higher levels of lubricant.
- 30 35. 14. A prosthesis comprising an extruded body (10, 150) having a wall extending in a thickness direction (t) between an inner surface (16, 152) and an outer surface (18, 154), extending along an axis (L) and formed of a single expanded polytetrafluoroethylene (PTFE) material, said wall having a microstructure of nodes (12) of solid material with flattened aspect and oriented transverse to said axis (L) and said nodes being interconnected by fibers (14), said extruded body having been stretched differently through its thickness and having been heated at elevated temperature to uniformly sinter and fix the nodal structure of said single material, whereby spaces between said nodes (12) define tapering channels extending along the wall thickness direction (t).
15. A prosthesis according to claim 14, wherein said extruded body (10, 150) is expanded with a local expansion ratio that varies by no more than about 10% along its length.
- 40 45. 16. A prosthesis according to claim 14, wherein said extruded body (10, 150) is a tube, and said tapering channels extend substantially through the wall of the tube.
17. A prosthesis according to claim 16, wherein a substantial portion of said nodes (12) extend entirely from the inner to the outer surface (16, 152; 18, 154) and the tapering channels are through-channels.
- 50 55. 18. A prosthesis according to claim 16, wherein said nodes (12) of flattened aspect oriented transverse to said axis are ring shaped nodes extending at least partly around the tube in a circumferential direction.
19. A prosthesis according to claim 14, wherein said extruded body is a tube, and said tapering channels extend at least partially through the wall of the tube, and said body further having a second group of pores of smaller dimension located part way through the wall.
20. Tube formed of a single expanded, porous fluoropolymer material which is uniformly sintered and has a longitudinal axis and a wall, the tube having a microstructure characterized by ring-shaped nodes interconnected by fibrils, a substantial plurality of the ring-shaped nodes each circumscribing the longitudinal axis of the tube, the wall further having a microstructure characterised by a second group of nodes smaller than the ring-shaped nodes and located along a radial region extending partway through the wall.
21. A tube according to claim 20, wherein the fluoropolymer material comprises a copolymer of tetrafluoroethylene

and a monomer selected from the group consisting of ethylene, chlorotrifluoroethylene, perfluorocalkoxytetrafluoroethylene, and fluorinated propylenes.

22. A tube according to claim 20 or claim 21, wherein the nodes define internodal through-pores, the through-pores providing substantially straight passageways which traverse from one surface of the tube to another.
- 5        23. A tube according to claim 20, wherein the ring shaped nodes and the second group of nodes define passageways having a size distribution for controlling the extent of tissue ingrowth.

10

### Patentansprüche

1. Verfahren zur Herstellung eines geformten, porösen Artikels, bestehend oder enthaltend die Schritte:
- 15        Formen eines Vorformlings (50, 50') aus einem einzigen Fluorpolymermaterial und einem Gleitmittel, worin eine Variation des Gleitmittels entlang einer Dimension des Vorformlings (50, 50') erfolgte,
- 20        Extrudieren des Vorformlings zu einem extrudierten Artikel, der eine Form hat und ein Gleitmittel aufweist, das entsprechend der Variation des Gleitmittels im Vorformling (50, 50') variiert,
- 25        Entfernen von Gleitmittel aus dem Artikel und Strecken des extrudierten Artikels, um einen porösen Artikel (10, 70, 150) mit vorgegebenen Porengrößen in verschiedenen Zonen des Artikels zu formen, wobei Porenvariationen in Zonen auftreten, in denen der extrudierte Artikel Variationen des Gleitmittels aufwies, und
- 30        Sintern des porösen Artikels in gestrecktem Zustand, um seine Abmessungen zu fixieren, wodurch ein gesinteter, poröser Artikel (10, 70, 150) aus einem einzigen Fluorpolymermaterial mit unterschiedlicher Porosität in vorher festgelegten Zonen geformt wird.
2. Verfahren nach Anspruch 1, worin der Schritt des Formens des Vorformlings (50, 50') das Formen mit einer Gleitmittelmenge umfaßt, die längs einer Richtung durch den Vorformling von einer Menge von nicht unter ca. 10 % bis zu einer Menge von nicht mehr als ca. 25 % variiert.
3. Verfahren nach Anspruch 1, worin der Vorformling (50, 50') mit Gleitmittelmengen in verschiedenen Zonen geformt ist, die so gewählt sind, daß ein Artikel mit einer Porengrößenverteilung bereitgestellt wird, die zumindest auf einem Teil des Artikels Gewebewachstum erlaubt, ohne einen Flüssigkeitsaustritt durch den Artikel zu erlauben.
4. Verfahren nach Anspruch 1, worin der Sinterschritt durchgeführt wird, um den porösen Artikel bei der Sintertemperatur des Einharz-Fluorpolymers gleichmäßig zu sintern.
- 40        5. Verfahren nach Anspruch 1, worin der Schritt des Formens eines Vorformlings (50, 50') das Formen eines Vorformlings in mehreren Schichten umfaßt, wobei mindestens zwei Schichten unterschiedliche Gleitmittelmengen aufweisen.
- 45        6. Verfahren nach Anspruch 1, worin der Schritt des Extrudierens das Formen eines röhrenförmigen, extrudierten Artikels umfaßt.
7. Verfahren nach Anspruch 6, worin der röhrenförmige, extrudierte Artikel mit einer Wandstärke von unter 2 mm geformt ist.
- 50        8. Verfahren nach Anspruch 6 oder 7, worin der Streckschritt durch Strecken in einer Geschwindigkeit von unter ca. 2 % pro Sekunde durchgeführt wird.
- 55        9. Verfahren nach Anspruch 1, worin der Schritt des Extrudierens das Extrudieren eines röhrenförmigen, extrudierten Artikels mit einem Hohlraum umfaßt und der Streckschritt das Strecken umfaßt, so daß radial ausgerichtete Knoten (12) erzeugt werden, die sich über den Hohlraum erstrecken und durch Fibrillen (14) miteinander verbunden sind, wobei die Räume zwischen den Knoten Durchgangsporen vom Hohlraum zu einer äußeren Oberfläche (18) des Artikels definieren.

10. Verfahren nach Anspruch 1, worin der Schritt des Formens eines Vorformlings (50, 50') das Formen eines Vorformlings umfaßt, der an verschiedenen Stellen entlang seines Querschnitts unterschiedliche Gleitmittel aufweist.
11. Verfahren nach Anspruch 10, worin die unterschiedlichen Gleitmittel Gleitmittel mit verschiedenen Dichten oder verschiedenen Viskositäten sind.
12. Verfahren nach Anspruch 1, worin der geformte, poröse Artikel (10, 70, 150) ein prothetischer Artikel ist und die Variation des Gleitmittels eine ausgewählte Variation der Gleitmittelmenge in der Richtung des Artikelquerschnitts ist.
13. Verfahren nach Anspruch 1, worin die Variation des Gleitmittels entlang eines Querschnitts von der Innen- zur Außenseite des Vorformlings (50, 50') eintritt und der Schritt des Streckens des extrudierten Artikels eine konische Porenstruktur herbeiführt, die sich von der Innen- zur Außenseite des Artikels erstreckt, wobei die Porenstruktur von kleineren Poren zu größeren Poren reicht, worin die größeren Poren in Zonen ausgebildet sind, in denen der Artikel höhere Gleitmittelmengen aufweist.
14. Prothese bestehend aus oder enthaltend einen extrudierten Körper (10, 150) mit einer Wand, die sich in einer Dickenrichtung (t) zwischen einer inneren Oberfläche (16, 152) und einer äußeren Oberfläche (18, 154) längs einer Achse (L) erstreckt und aus einem einzigen, ausgedehnten Polytetrafluorethylenmaterial (PTFE) geformt ist, wobei die Wand eine Mikrostruktur von Knoten (12) aus festem Material mit abgeflachter Gestalt und quer zur Achse (L) ausgerichtet hat und die Knoten miteinander durch Fasern (14) verbunden sind, wobei der extrudierte Körper über seine Dicke unterschiedlich gestreckt und bei höherer Temperatur erhitzt wurde, um die knotenartige Struktur des einzigen Materials gleichmäßig zu sintern und zu fixieren, wodurch Räume zwischen den Knoten (12) konische Kanäle definieren, die sich entlang der Wandstärkenrichtung (t) erstrecken.
15. Prothese nach Anspruch 14, wobei der extrudierte Körper (10, 150) mit einer lokalen Ausdehnungsrate ausgedehnt ist, die über seine Länge um nicht mehr als ca. 10 % variiert.
16. Prothese nach Anspruch 14, wobei der extrudierte Körper (10, 150) eine Röhre ist und die konischen Kanäle sich wesentlich durch die Röhrenwand erstrecken.
17. Prothese nach Anspruch 16, worin sich ein wesentlicher Teil der Knoten (12) vollständig von der inneren zur äußeren Oberfläche (16, 152; 18, 154) erstreckt und die konischen Kanäle Durchgangskanäle sind.
18. Prothese nach Anspruch 16, wobei die Knoten (12) mit abgeflachter Gestalt und quer zur Achse ausgerichtet ringförmige Knoten sind, die sich zumindest teilweise in Kreislinienrichtung um die Röhre erstrecken.
19. Prothese nach Anspruch 14, wobei der extrudierte Körper eine Röhre ist und die konischen Kanäle sich zumindest teilweise durch die Röhrenwand erstrecken und der Körper außerdem eine zweite Gruppe Poren mit kleineren Maßen hat, die sich teilweise durch die Wand erstrecken.
20. Röhre, geformt aus einem einzigen, ausgedehnten, porösen Fluorpolymermaterial, die gleichmäßig gesintert ist und eine Längsachse und eine Wand hat, wobei die Röhre eine Mikrostruktur aufweist, die durch ringförmige Knoten gekennzeichnet ist, die durch Fibrillen miteinander verbunden sind, wobei eine deutliche Mehrzahl der ringförmigen Knoten jeweils kreislinienförmig um die Längsachse der Röhre angeordnet ist und außerdem die Wand eine Mikrostruktur hat, die durch eine zweite Gruppe von Knoten gekennzeichnet ist, die kleiner als die ringförmigen Knoten sind und sich entlang einer radialen Zone befinden, die sich teilweise durch die Wand erstreckt.
21. Röhre nach Anspruch 20, wobei das Fluorpolymermaterial aus einem Copolymer aus Tetrafluorethylen und einem Monomer, ausgewählt aus der Gruppe bestehend aus Ethylen, Chlortrifluorethylen, Perfluoralkoxytetrafluorethylen und fluorierten Propylenen, besteht oder dieses enthält.
22. Röhre nach Anspruch 20 oder 21, worin die Knoten intermodale Durchgangsporen definieren, die im wesentlichen gerade Verbindungsgänge bereitstellen, die von einer Oberfläche der Röhre zu einer anderen durchgehen.
23. Röhre nach Anspruch 20, worin die ringförmigen Knoten und die zweite Gruppe Knoten Verbindungsgänge definieren, die eine Größenverteilung zur Regelung des Ausmaßes des Gewebeeinwachsens aufweisen.

**Revendications**

1. Méthode de production d'un article poreux mis en forme comprenant les étapes consistant à
  - 5      mettre en forme un lingot (50, 50') d'un matériau fluoropolymère unique et d'un lubrifiant dans lequel une variation du lubrifiant a été établie le long d'une des dimensions du lingot (50, 50')
    - 10     extruder le lingot pour former un article extrudé ayant une forme et un lubrifiant qui varie de manière correspondant à la variation du lubrifiant dans le lingot (50, 50')
    - 15     enlever le lubrifiant de l'article et étirer l'article extrudé pour former un article poreux (10, 70, 150) avec des dimensions de pores prédéterminées dans différentes régions de celui-ci, dans lequel les variations des pores se produisent dans des régions dans lesquelles l'article extrudé comprenait les variations du lubrifiant, et friter l'article poreux dans son état étiré pour fixer ses dimensions, de manière à former ainsi un article poreux fritté (10, 70, 150) d'un matériau fluoropolymère unique possédant des porosités différentes dans des régions prédéterminées.
2. Méthode selon la revendication 1, dans laquelle l'étape de mise en forme du lingot (50, 50') comprend la mise en forme avec un niveau de lubrifiant qui varie le long d'une direction traversant le lingot d'un niveau non inférieur à environ dix pour cent jusqu'à un niveau non supérieur à environ vingt quatre pour cent.
- 20    3. Méthode selon la revendication 1, dans laquelle le lingot (50, 50') est mis en forme avec des niveaux de lubrifiant dans différentes régions déterminées de manière à conduire à un article ayant une distribution de taille de pores qui permet la croissance tissulaire sur au moins une partie de l'article tout en prévenant des fuites de liquide à travers l'article.
- 25    4. Méthode selon la revendication 1, dans laquelle l'étape de fritage est réalisée de manière à friter uniformément l'article poreux à la température de fritage de ladite résine fluoropolymère unique.
- 5      5. Méthode selon la revendication 1, dans laquelle l'étape de mise en forme du lingot (50, 50') comprend la mise en forme d'un lingot en une pluralité de couches, au moins deux couches ayant des niveaux différents de lubrifiant.
- 30    6. Méthode selon la revendication 1, dans laquelle l'étape d'extrusion comprend la mise en forme d'un article extrudé tubulaire.
- 35    7. Méthode selon la revendication 6, dans laquelle on forme l'article tubulaire extrudé avec une épaisseur des parois inférieure à deux millimètres.
8. Méthode selon la revendication 6 ou 7, dans laquelle l'étape d'étrage est réalisée par étrage à un taux approximativement inférieur à deux pour cent par seconde.
- 40    9. Méthode selon la revendication 1, dans laquelle l'étape d'extrusion comprend l'extrusion d'un article tubulaire extrudé possédant une lumière, et l'étape d'étrage comprend l'étrage de manière à produire des noeuds orientés radialement (12) s'étendant à proximité de la lumière et interconnectés par des fibrilles (14), les espaces entre les noeuds définissant des pores traversants de ladite lumière vers la surface externe (18) de l'article.
- 45    10. Méthode selon la revendication 1, dans laquelle l'étape de mise en forme d'un lingot (50, 50') comprend la mise en forme d'un lingot ayant différents lubrifiants à différentes positions le long d'une coupe transversale.
11. Méthode selon la revendication 10, dans laquelle les différents lubrifiants sont des lubrifiants de densité différente ou de viscosité différente.
- 50    12. Méthode selon la revendication 1, dans laquelle l'article formé poreux mis en forme (10, 70, 150) est un article de prothèse, et la variation du lubrifiant est une variation sélectionnée du niveau du lubrifiant dans la direction de la section transversale de l'article.
- 55    13. Méthode selon la revendication 1, dans laquelle la variation du lubrifiant a lieu le long d'une section transversale de l'intérieur vers l'extérieur dudit lingot (50, 50'), et l'étape d'étrage de l'article extrudé introduit une structure poreuse conique s'étendant de l'intérieur vers l'extérieur de l'article, la structure poreuse s'étendant des pores les plus petits vers les pores les plus grands, dans laquelle les pores les plus grands sont formés dans des régions

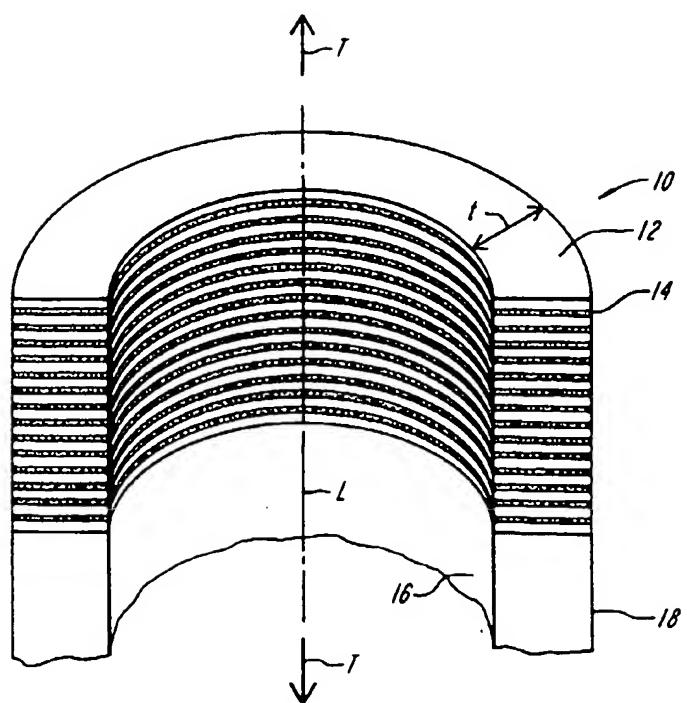

dans lesquelles l'article a les niveaux les plus élevés en lubrifiant.

14. Prothèse comprenant un corps extrudé (10, 150) ayant une paroi s'étendant dans une direction de l'épaisseur (t) entre une surface interne (16, 152) et une surface externe (18, 154), s'étendant le long d'un axe (L) et formée d'un matériau en un polytétrafluoroéthylène (PTFE) expansé unique, ladite paroi ayant une microstructure de noeuds (12) d'un matériau solide présentant un aspect aplati et orienté transversalement audit axe (L) et lesdits noeuds étant interconnectés par des fibres (14), ledit corps extrudé ayant été étiré différemment à travers son épaisseur et ayant été chauffé à une température élevée pour friter et fixer uniformément la structure nodale dudit matériau unique, les espaces entre lesdits noeuds (12) définissant des canaux coniques s'étendant le long de la paroi dans la direction de son épaisseur (t).
15. Prothèse selon la revendication 14, dans laquelle ledit corps extrudé (10, 150) est expansé avec un coefficient d'expansion locale qui varie de pas plus d'environ 10 % le long de sa longueur.
16. Prothèse selon la revendication 14, dans laquelle ledit corps extrudé (10, 150) est un tube, et lesdits canaux coniques s'étendant essentiellement à travers la paroi du tube.
17. Prothèse selon la revendication 16, dans laquelle une partie substantielle desdits noeuds (12) s'étend entièrement de la surface interne vers la surface externe (16, 152 ; 18, 154) et les canaux traversants.
18. Prothèse selon la revendication 16, dans laquelle lesdits noeuds (12) d'aspect aplati orientés transversalement audit axe sont des noeuds en forme d'anneaux s'étendant au moins en partie autour du tube de la direction circonférentielle.
19. Prothèse selon la revendication 14, dans laquelle ledit corps extrudé (10, 150) est un tube, et lesdits canaux coniques s'étendent au moins partiellement à travers les parois du tube, ledit corps ayant en outre un second groupe de pores de dimension plus petite positionné sur une part du trajet à travers la paroi.
20. Tube formé d'un matériau poreux fluoropolymère unique expansé, uniformément fritté, ayant un axe longitudinal et une paroi, et une microstructure caractérisé par des noeuds de forme annulaire interconnectés par des fibrilles, une pluralité de ces noeuds annulaires entourant chacun l'axe longitudinal de tube, la paroi ayant en outre une microstructure, caractérisé par un second groupe de noeuds plus petits que les noeuds annulaires et situé le long d'une région radiale s'étendant sur une partie du trajet à travers la paroi.
21. Tube selon la revendication 20, dans lequel le matériau en fluoropolymère comprend un copolymère de tétrafluoroéthylène et un monomère choisi parmi le groupe consistant en éthylène, chlorotrifluoroéthylène, perfluoroalkoxytétrafluoroéthylène, et propylènes fluorés.
22. Tube selon la revendication 20 ou 21, dans lequel les noeuds définissent des pores traversants internodaux, les pores traversants fourissant des passages substantiellement rectilignes qui traversent d'une surface du tube à l'autre.
23. Tube selon la revendication 20, dans lequel les noeuds en forme d'anneaux et le second groupe de noeuds définissent des passages ayant une distribution de taille destinée à limiter l'étendue de la croissance tissulaire.
